Classification of Breast Cancer Clinical Stage with Gene Expression Data

Zhu Wang UT Health San Antonio wangz1@uthscsa.edu

April 29, 2020

This document presents analysis for the MAQC-II project, human breast cancer data set with boosting algorithms developed in Wang (2018a,b) and implemented in R package bst.

Dataset comes from the MicroArray Quality Control (MAQC) II project and includes 278 breast cancer samples with 164 estrogen receptor (ER) positive cases. The data files GSE20194_series_matrix.txt.gz and GSE20194_MDACC_Sample_Info.xls can be downloaded from http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?token=rhojvaiwkcsaihq&acc=GSE20194. After reading the data, some unused variables are removed. From 22283 genes, the dataset is pre-screened to obtain 3000 genes with the largest absolute values of the two-sample t-statistics. The 3000 genes are standardized.

```
# The data files below were downloaded on June 1, 2016
require("gdata")
bc <- t(read.delim("GSE20194_series_matrix.txt.gz", sep = "",</pre>
    header = FALSE, skip = 80))
colnames(bc) <- bc[1, ]</pre>
bc \leftarrow bc[-1, -c(1, 2)]
### The last column is empty with variable name
### !series_matrix_table_end, thus omitted
bc \leftarrow bc[, -22284]
mode(bc) <- "numeric" ### convert character to numeric</pre>
dat1 <- read.xls("GSE20194_MDACC_Sample_Info.xls", sheet = 1,</pre>
    header = TRUE)
y <- dat1$characteristics..ER_status
y < - ifelse(y == "P", 1, -1)
table(y)
res <- rep(NA, dim(bc)[2])
for (i in 1:dim(bc)[2]) res[i] <- abs(t.test(bc[, i] ~ y)$statistic)</pre>
### find 3000 largest absolute value of t-statistic
tmp <- order(res, decreasing = TRUE)[1:3000]
dat <- bc[, tmp]
### standardize variables
dat <- scale(dat)</pre>
```

Set up configuration parameters.

```
nrun <- 100
per \leftarrow c(0, 0.05, 0.1, 0.15)
learntype <- c("tree", "ls")[2]</pre>
tuning <- "error"</pre>
n.cores <- 4
plot.it <- TRUE
### robust tuning parameters used in bst/rbst function
s \leftarrow c(0.9, 1.01, 0.5, -0.2, 0.8, -0.5, -0.2)
nu \leftarrow c(0.01, 0.1, 0.01, rep(0.1, 4))
m <- 100 ### boosting iteration number
### whether to truncate the predicted values in each boosting
### iteration?
ctr.trun <- c(TRUE, rep(FALSE, 6))
### used in bst function
bsttype <- c("closs", "gloss", "qloss", "binom", "binom", "hinge",
    "expo")
### and corresponding labels
bsttype1 <- c("ClossBoost", "GlossBoost", "QlossBoost", "LogitBoost",
    "LogitBoost", "HingeBoost", "AdaBoost")
### used in rbst function
rbsttype <- c("closs", "gloss", "qloss", "tbinom", "binomd",
    "thinge", "texpo")
### and corresponding labels
rbsttype1 <- c("ClossBoostQM", "GlossBoostQM", "QlossBoostQM",
    "TLogitBoost", "DlogitBoost", "THingeBoost", "TAdaBoost")
```

The training data contains randomly selected 50 samples with positive estrogen receptor status and 50 samples with negative estrogen receptor status, and the rest were designated as the test data. The training data is contaminated by randomly switching response variable labels at varying pre-specified proportions per=0, 0.05, 0.1, 0.15. This process is repeated nrun=100 times. The base learner is learntype=ls (with quotes). To select optimal boosting iteration from maximum value of m=100, we run five-fold cross-validation averaging classification errors. In cross-validation, we set the number of cores for parallel computing by n.cores=4. Selected results can be plotted if plot.it=TRUE. Gradient based boosting includes ClossBoost, GlossBoost, QlossBoost, LogitBoost, HingeBoost and AdaBoost. Robust boosting using rbst contains ClossBoostQM, GlossBoostQM, QlossBoostQM, TLogitBoost, DlogitBoost, THingeBoost and TAdaBoost.
